

High-Resolution Cryo-Electron Tomography – Current State and Future Prospects

Sebastian Tacke & Stefan Raunser

Max Planck Institute for Molecular Physiology

Department of Structural Biochemistry

- Structure and function of macromolecules are highly interdependent.
- Multiple structures of different functional states help to understand molecular mechanisms.
- *In situ* structures help to understand how molecules interact with their native environment.
- Structures can be used as starting point to design functional experiments (e.g. by guided design of mutations).

X-Ray Crystallography

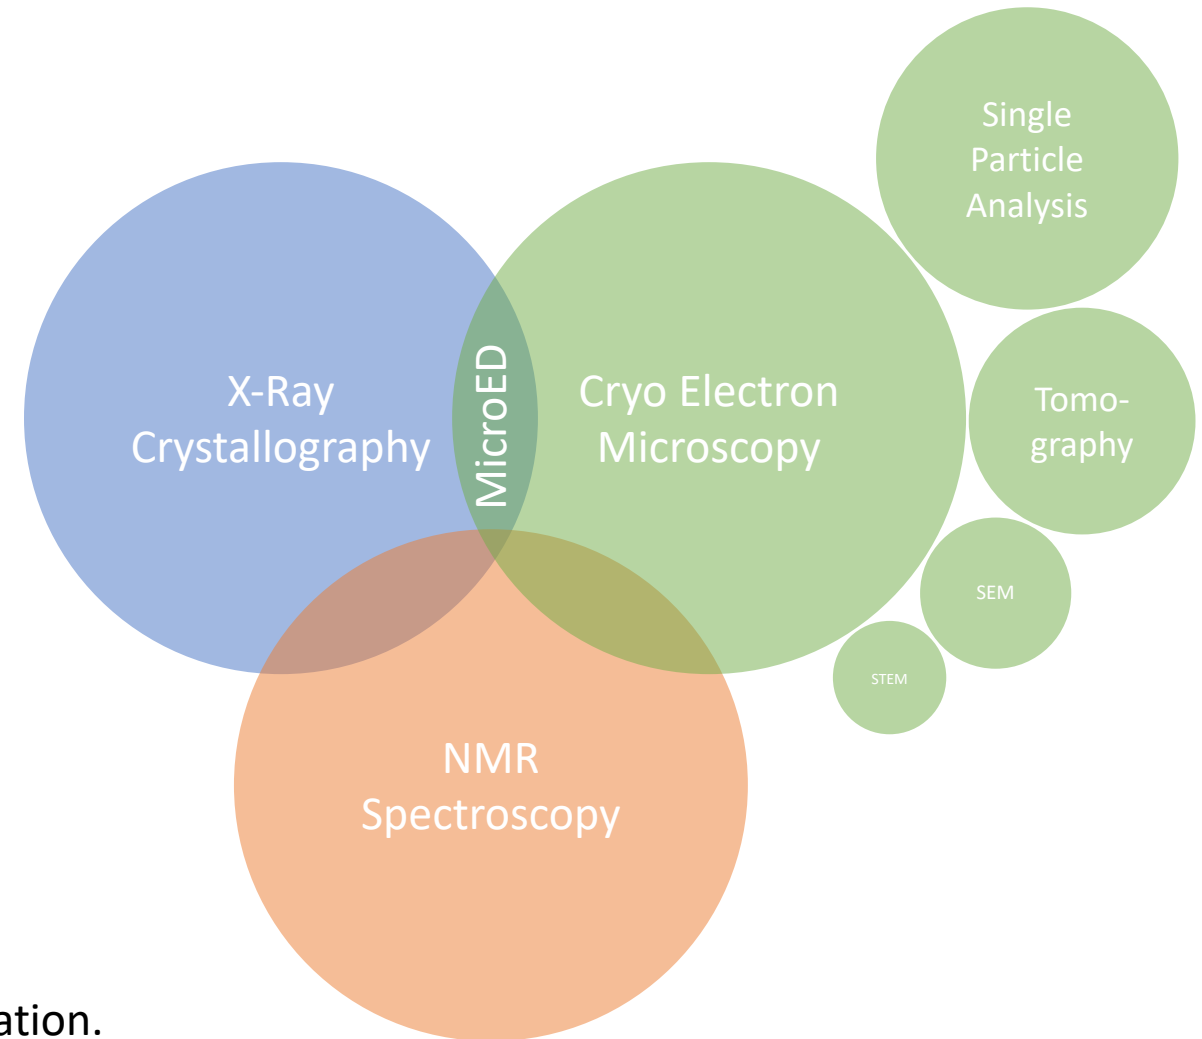

- Can be very quick and easy.
- No principle limitations for protein size etc.
- Large amounts of highly pure material necessary.
- Protein needs to form highly ordered crystals.
- Phase problem needs to be solved.

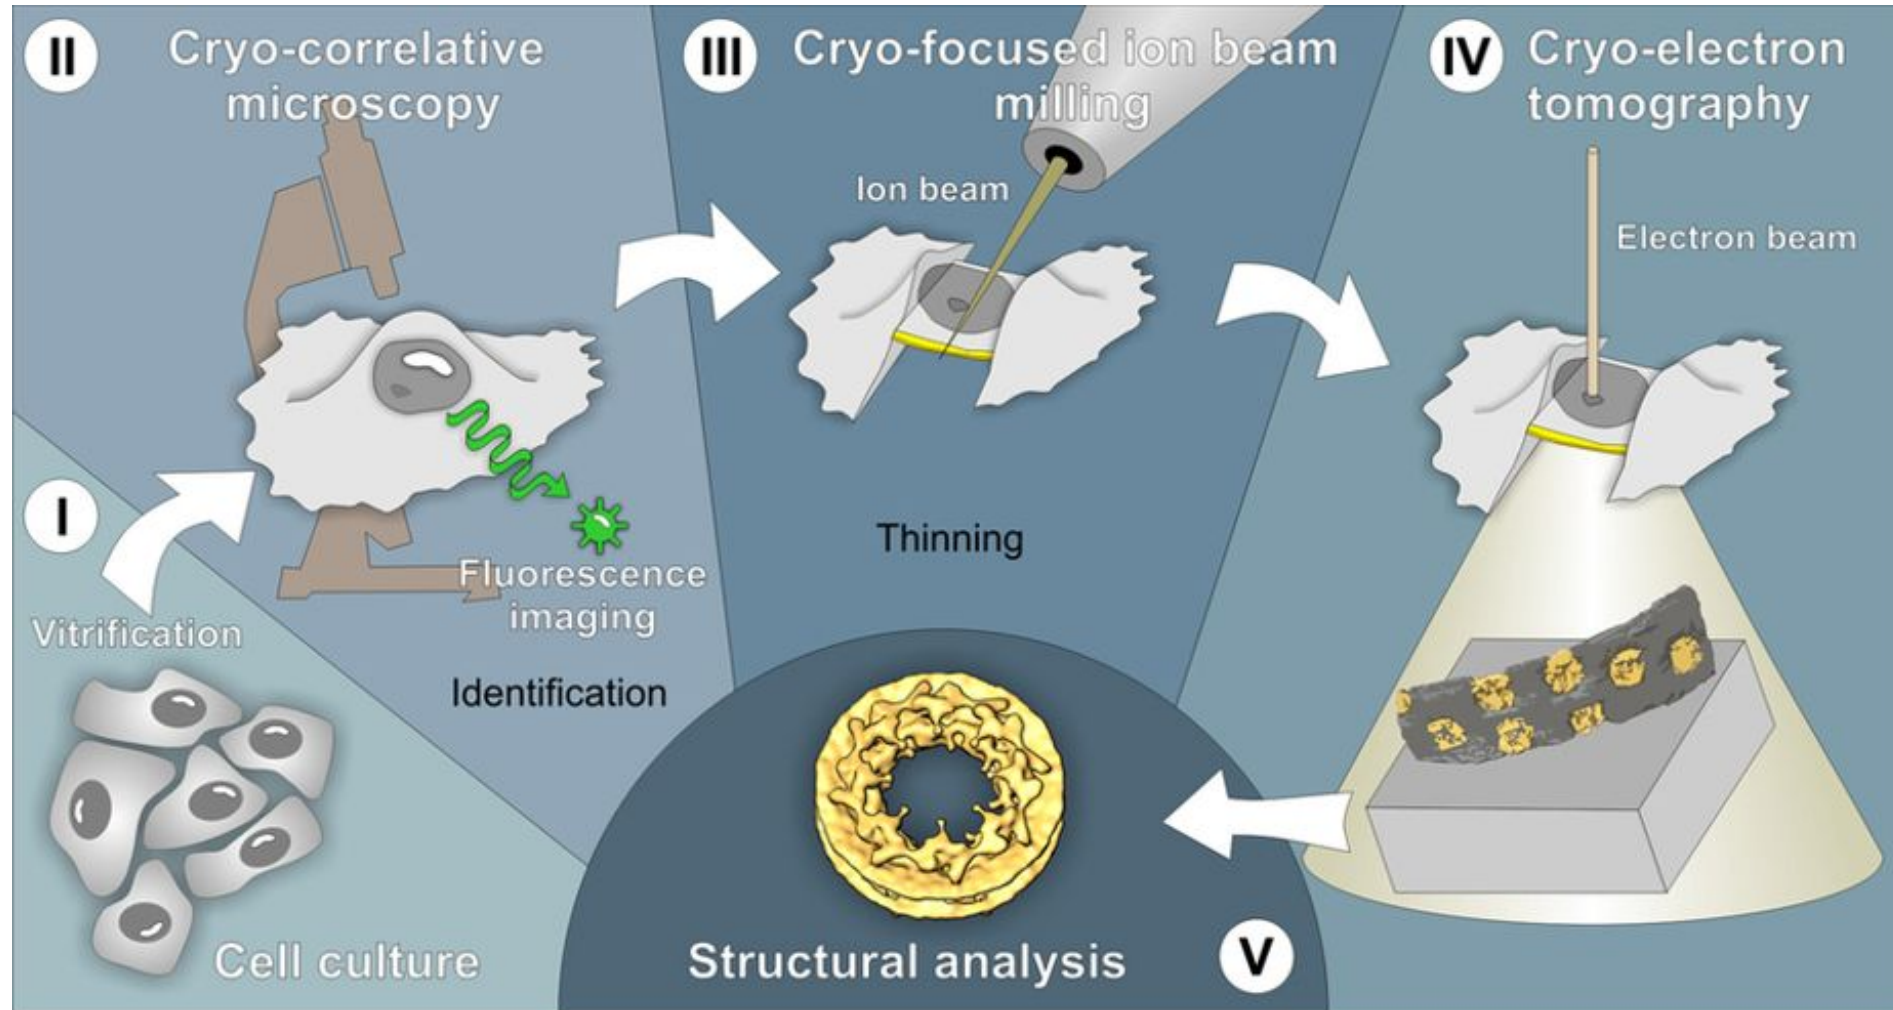

NMR Spectroscopy

- True solution method.
- Accounts for dynamics in macromolecules.
- In-cell NMR is possible in some cases.
- Requires labelling with heavy nuclides (N2, C13, N15).
- Limited to small proteins or selective labelling.
- Sample needs to be extraordinarily stable.

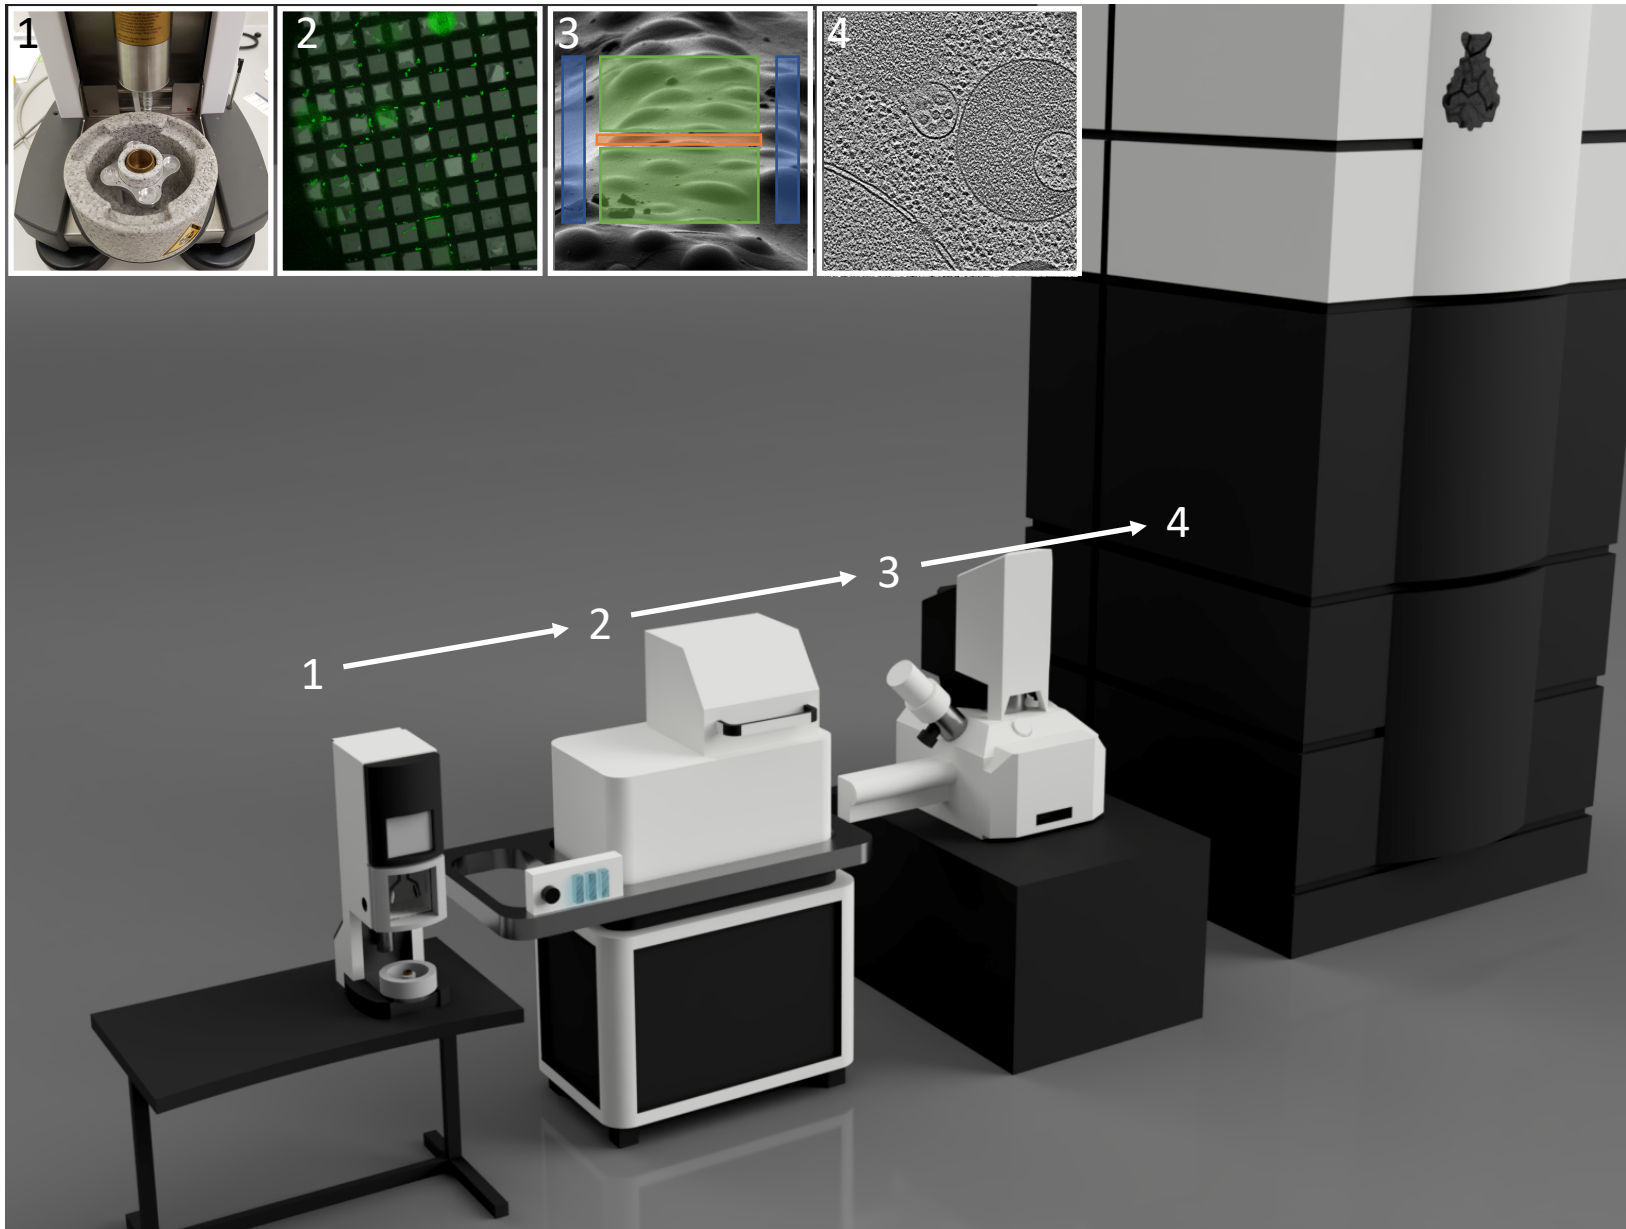

Cryo Electron Microscopy (Single Particle Analysis)

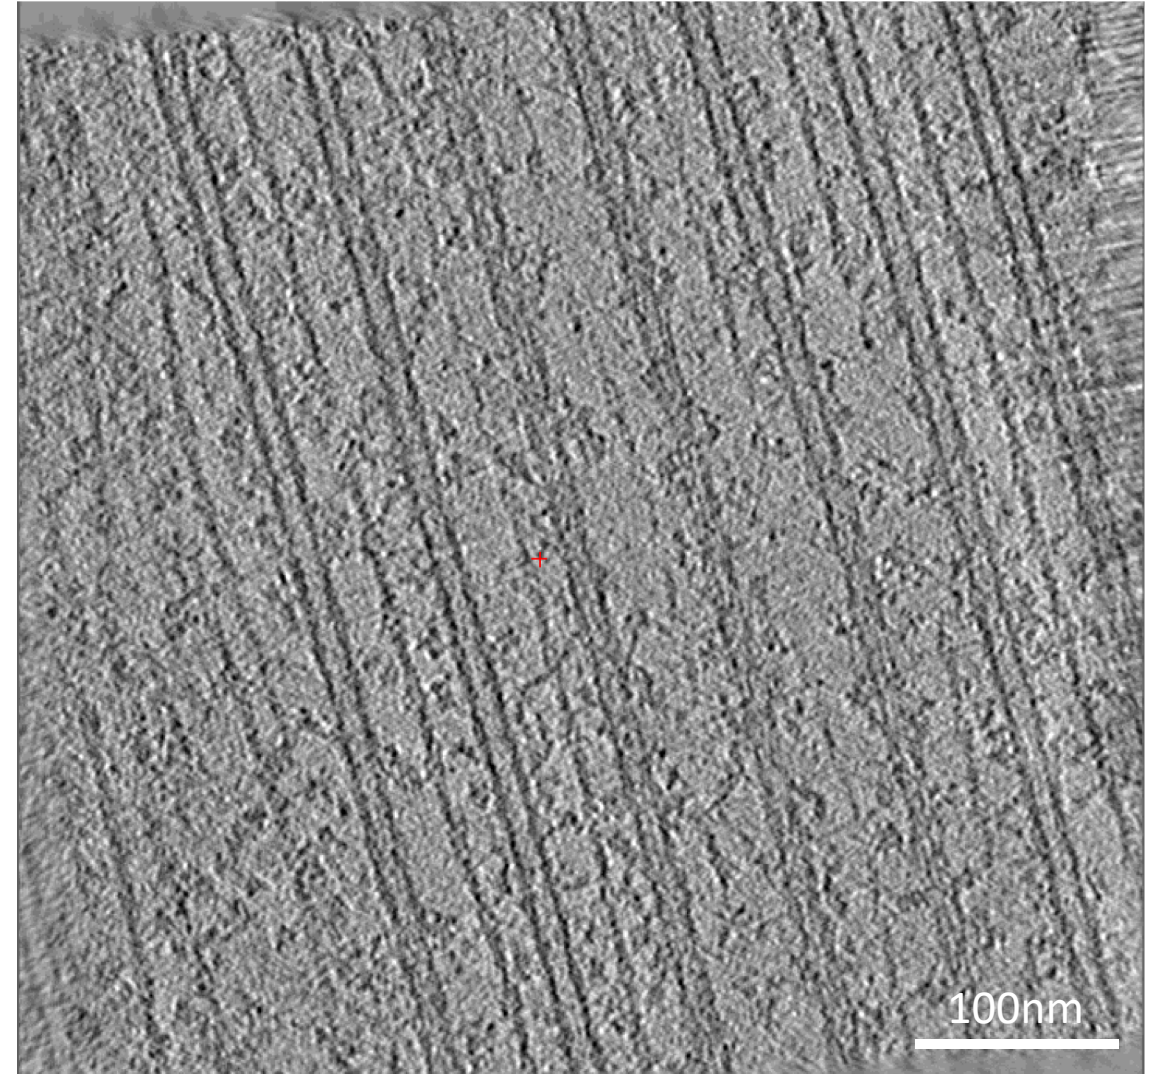

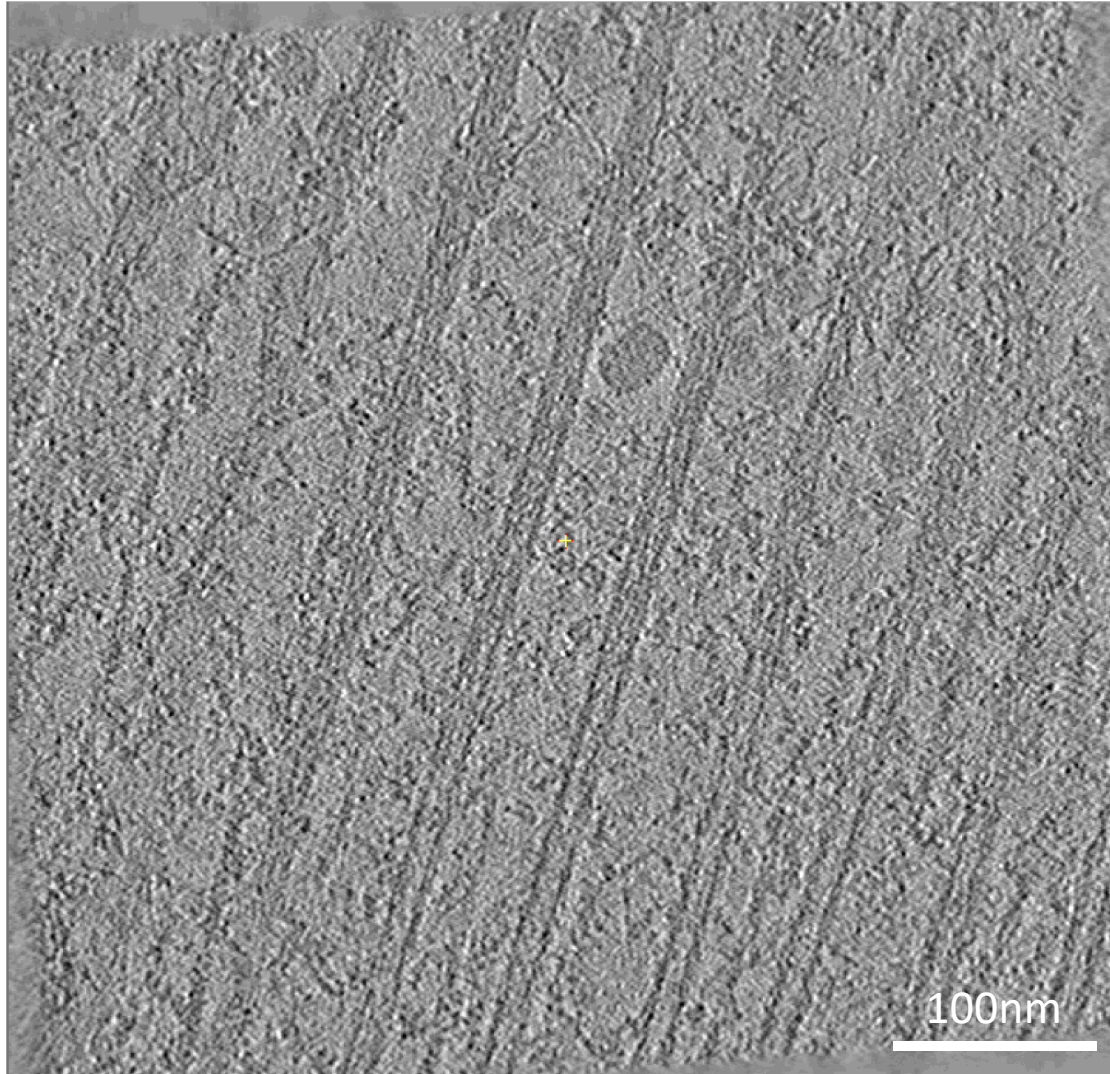

- Lower sample amounts necessary.
- Proteins do not need to be crystallized.
- Not always easy to find good conditions for sample preparation.
- Sample preparation might be harmful for the protein.
- Difficult for smaller molecules.

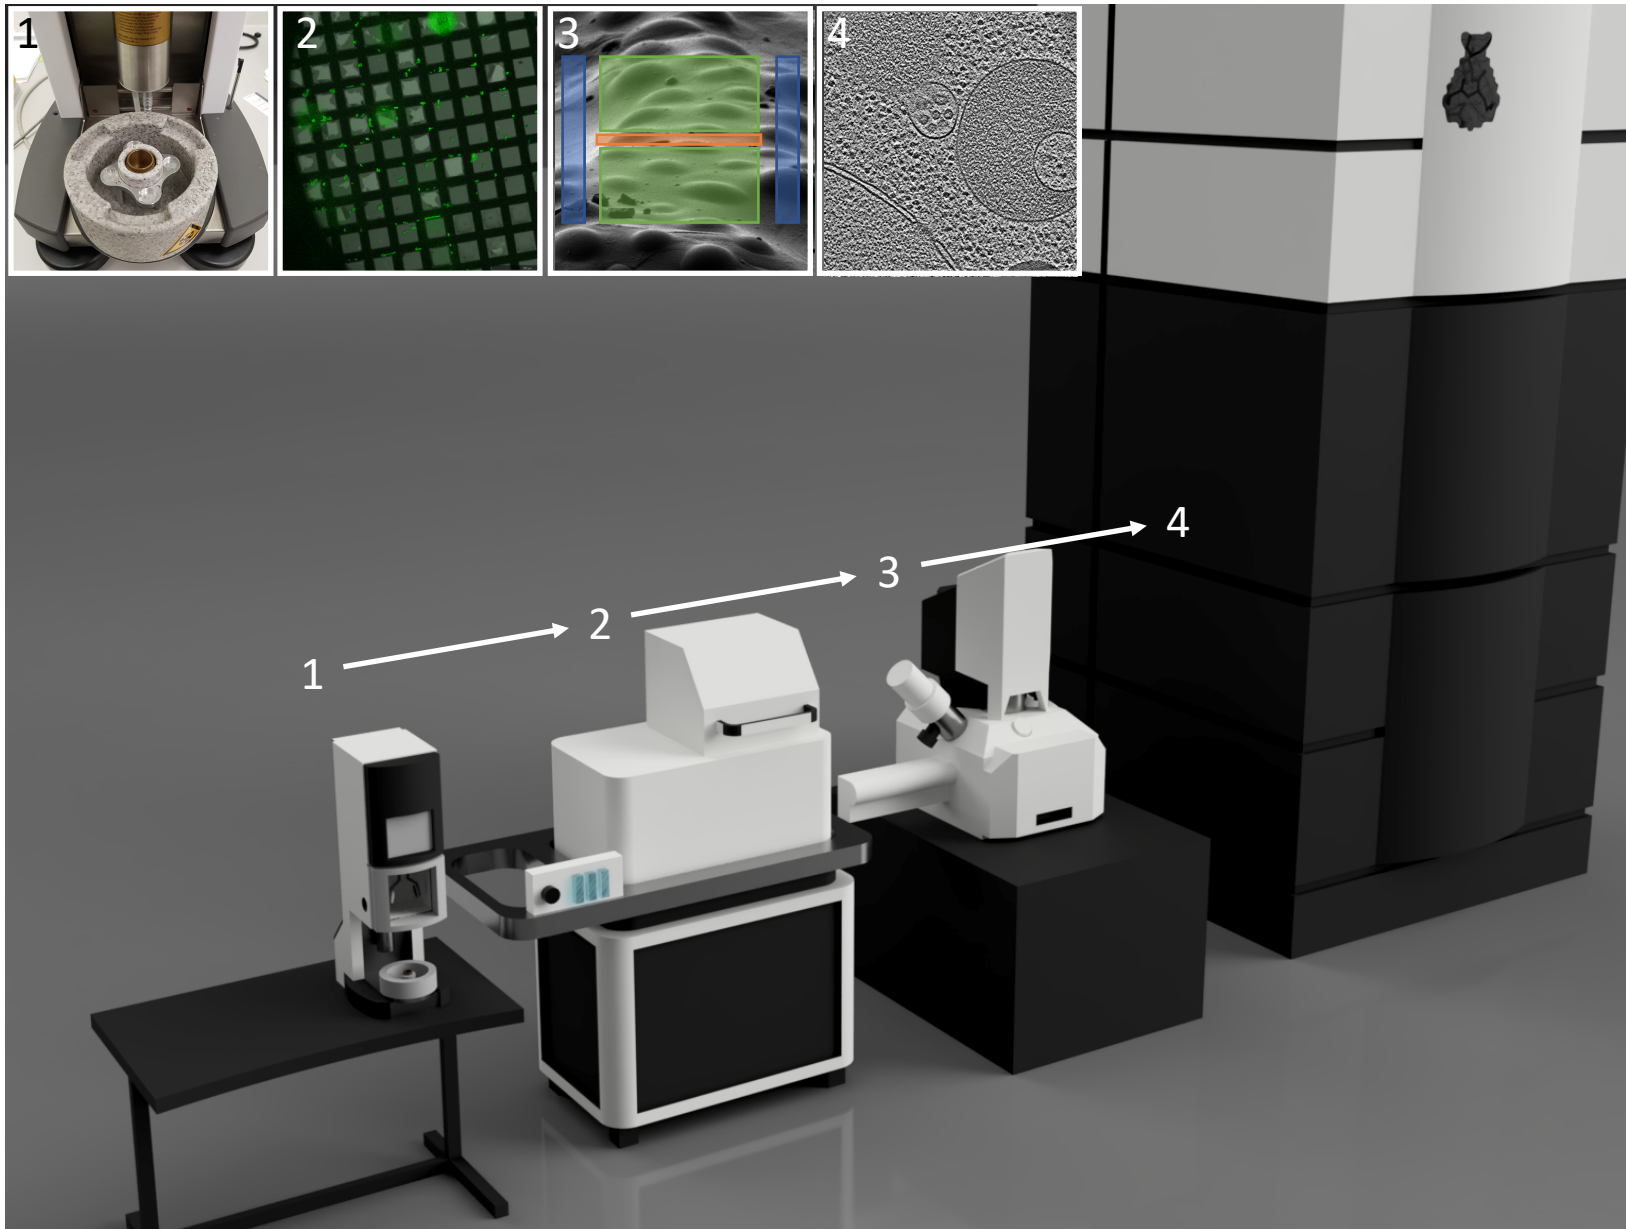

Cryo Electron Tomography

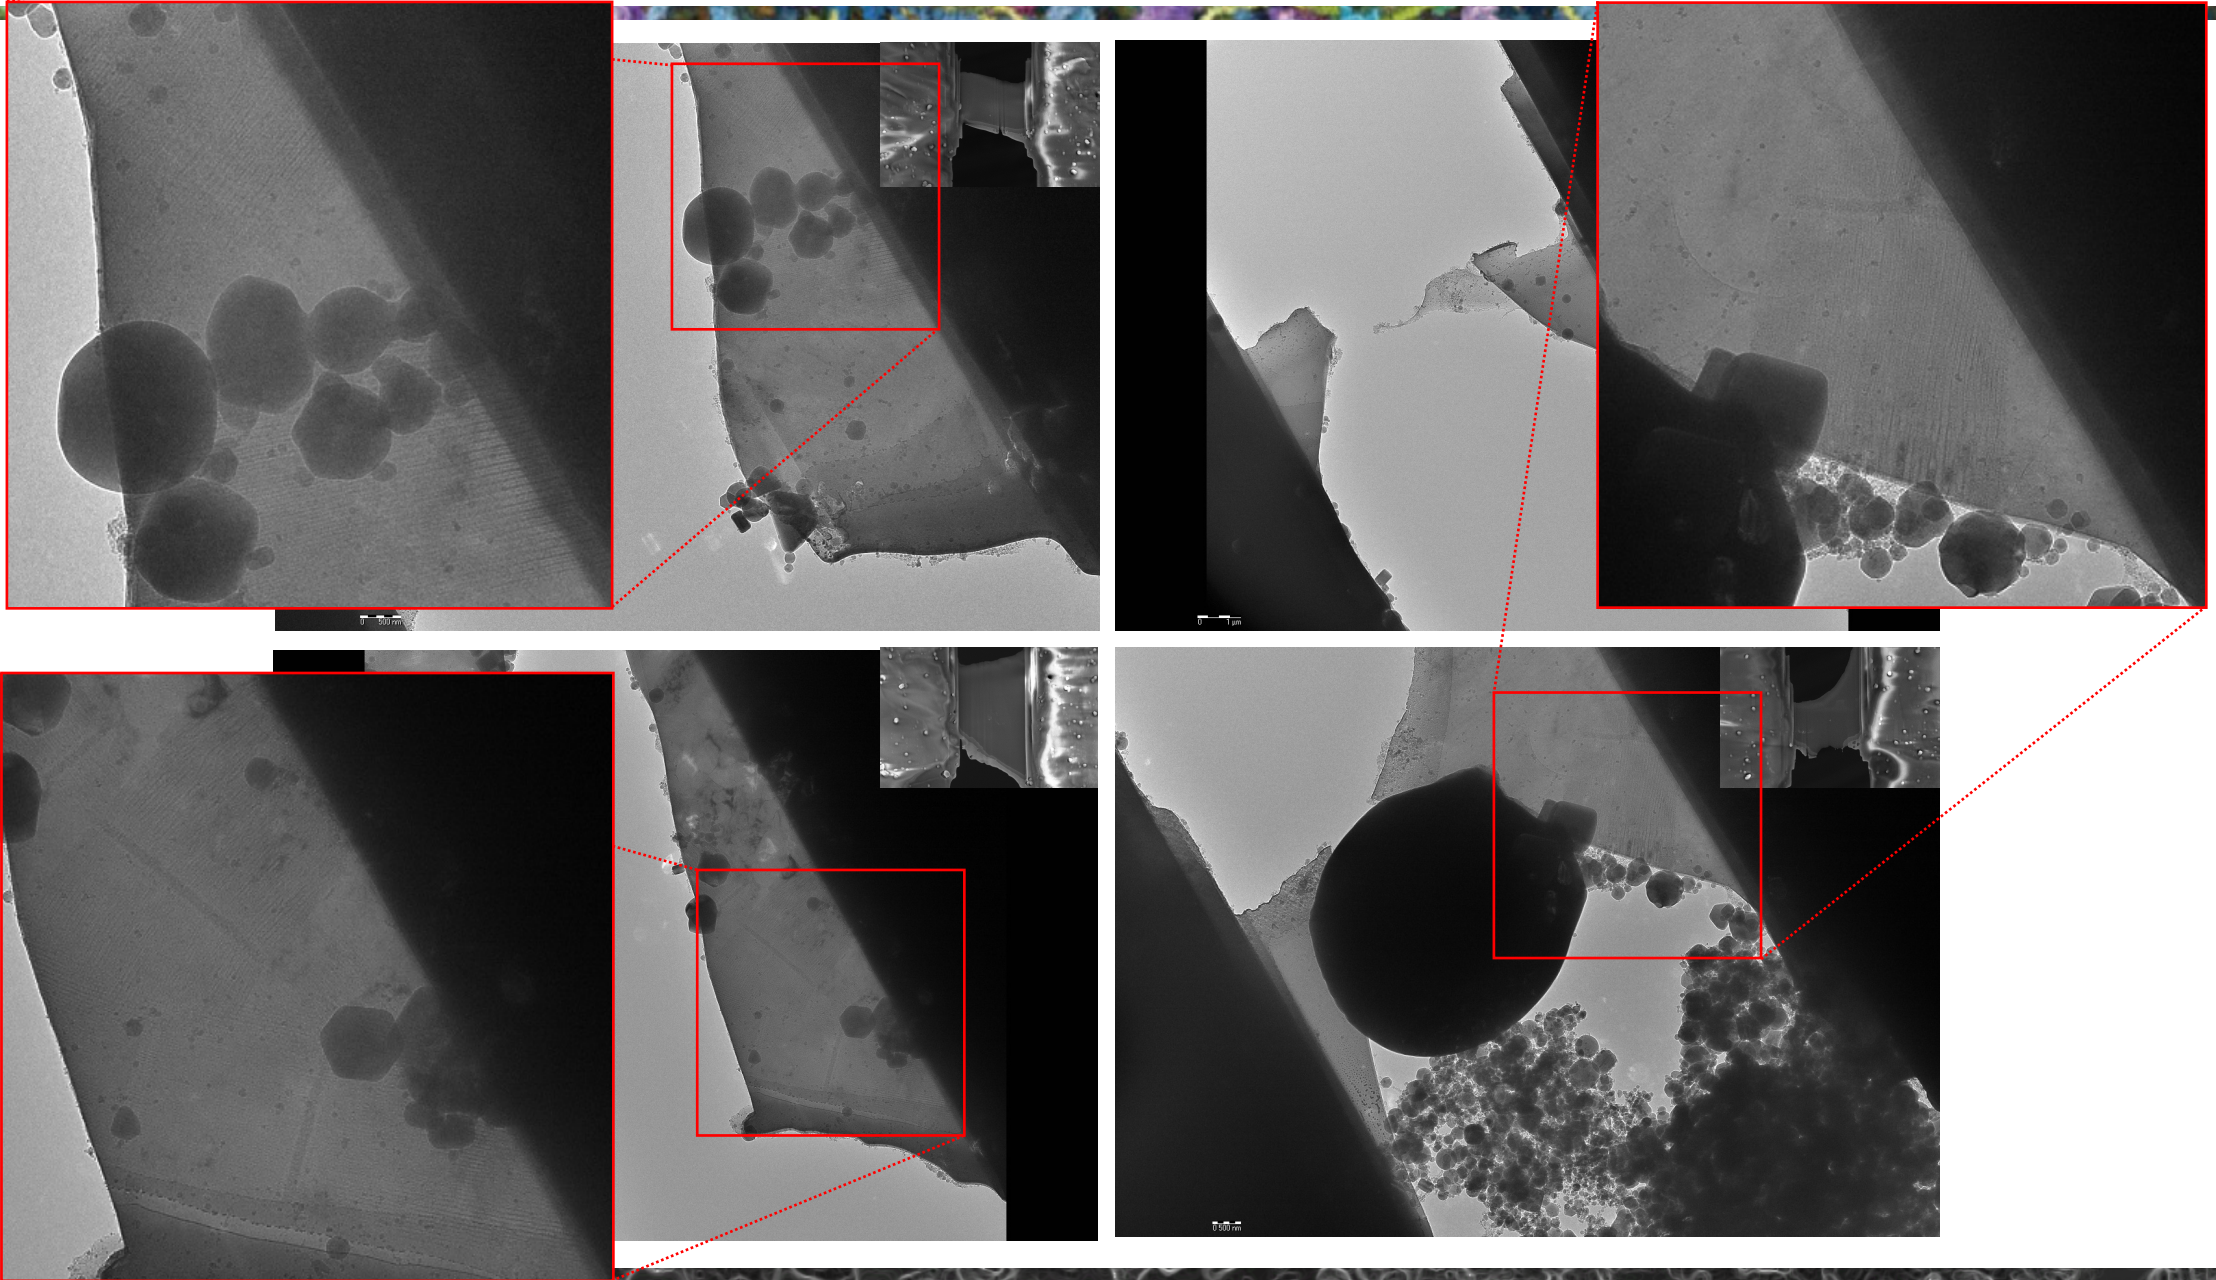

Cryo Electron Tomography

Artefacts

1500 tomograms with thickness below 150 nm.

Current performance

Approx. 10 lamellae per Day (8h)

Approx. one month for one dataset

Approx. two month of data acquisition

Target performance

30 lamellae per day

Approx. 10 days for one dataset

Approx. two weeks of data acquisition

Current limitations:

1. Reliable vitrification
2. Artefact free transfer.
3. Reduced contamination rate.
4. Automated milling missing.
5. Faster data acquisition.
